TITLE: Main Transportation Lines Operated by Means of Belt Conveyers and Cables (Magistral'nyy transport s pomoshch'yu lentoknykh konveyerov i kanatnykh dorog)

PERIODICAL: Mekhanizatsiya trudoyemkikh i tyazhelykh rabot, 1958, <sup>12</sup>Nr 9, pp 22-25 (USSR)

ABSTRACT: Referring to the advantages of belt conveyer and suspended cable transportation of bulk goods in the US, South America and Sweden, the author admits that the USSR is lagging behind in this respect. The VNIPTMASH Institute is working on this problem. By means of various graphs, computations and reflections, the author tries to find out the most rational ways of transportation.  
There are 3 photographs and 10 graphs.

TITLE: Pelletizing Krivoy Rog Ores (Okatyshi iz krivorozhskikh rud)

PERIODICAL: V sb.: Domennoye proiz-vo. Moscow, Metallurgizdat, 1957, pp 74-88

ABSTRACT: An investigation is made of the production of pellets (P) from undersize (0-12 mm) Krivoy Rog ores (KR). The experiments were preceded by the testing of a number of methods of clinkering. The best results were obtained when dry material was introduced into a supersaturated moist mass, with subsequent pelletizing. Experiments showed that clinkering by pelletizing may be done successfully not only with fine-ground concentrates, but also with undersize KR. Flue dust, lime, chalk, and coke breeze were tested in a series of experiments to strengthen the P. The P thus produced were roasted with blast-furnace gas. The influence of the temperature and of the excess-air coefficient during the burning of the charge additions on the roasting process and the properties of the P were investigated. The rate of downward travel of the zone of combustion

Russian. Experiments were made on a batch of soda glass. The batch was melted in a  
to be used as hot briquettes for 800–1400°C. The melting process was carried out  
under some of the silicate-forming conditions and the results were compared with  
the agglomeration converters. The results show that the agglomeration converters  
do not lead to any pronounced changes in the properties of the glass. The results  
show that the use of the agglomeration converters is not recommended for the  
production of soda glass and the use of the agglomeration converters is not  
recommended for the production of soda glass. The results show that the use of the  
agglomeration converters is not recommended for the production of soda glass.

TITLE: Semi-Industrial Investigations of the Thermal Preparation of Glass Layers (Polupromyshlennyye issledovaniya termicheskoy podgotovki stekol'nykh shikht)

PERIODICAL: Steklo i keramika, 1958, Nr 7, pp. 17 - 24 (USSR)

ABSTRACT: Such a sintering device is shown in figures 1 and 2 and is described afterwards. The tests were carried out with two types of layers: the test-and the working layer, the compositions of which are given in table 1. The curves of the rise in temperature during the sintering of the two layers under the same conditions, are given in figure 3. The curves of the dependence of the  $\text{Na}_2\text{SO}_4$ -content in finished agglomerates on the relation of gas and air in the induction mixture for 2 sulfate-soda layers are given in figure 4, and are described in full details. The temperature curves obtained with the sintering of the test layer are given in figure 5. Further the authors report on the filling weight of the agglomerated glass layers, as well as also on the productiveness of the agglomerates. The most advantageous height

Card 1/3

Semi-Industrial Investigations of the Thermal Preparation of Glass Layers

SOV/72-58-7-5/19

of layer during sintering, as well as the optimum velocities of this process are given in table 2. The duration of the heat treatment, as well as the curves of vacuum-changes for different types of layers and heights are given (Figures 6,7 and 8). The heat-treatment lasts 9 to 10 minutes. Then, the consumption of loosening- and foundation material, as well as the gas consumption for the heat treatment of the layer are given. The dependence of the specific gas consumption on the excessive air supply for various layers is shown (Fig 9). The recommended gas processes for some glass-layers are given in table 3. The dependence of the gas consumption on the duration of the heat treatment and the sintering speed are illustrated by means of curves (Figs 10 and 11). Such a device has been developed for a tank furnace of the Gomel' Glass-Works on the basis of the semi-industrial tests carried out. A test series of the glass melting of heat-treated layers was carried out by which the technical and economic efficiency of their industrial use was proved. There are 11 figures, 3 tables, and 2 Soviet references.

TITLE: The Influence of Thermal Preparation of the Charge on Glass Frits

PERIODICAL: Steklo i keramika, 1959, Nr 10, pp 21 - 27 (USSR)

ABSTRACT: In the years 1952-1954, the Moskovskiy gornyy institut (Moscow Mining Institute) together with the Gomel' Glassworks carried out investigations of the thermal preparation of glass charges (Footnote 1). Experiments on the melting of the sintered charge in continuous glass-melting furnaces were carried out at the Gomel' Glassworks, and experiments of comparative melting concerning the initial and the sintered charge were carried out at the laboratory of the first Kafedra silikatov i stekla Belorusskogo politekhnicheskogo instituta (Chair for Silicates and Glass of the Belorussian Polytechnic Institute), at the Laboratory for Glass Melting, as well as at the test plant of the institut stekla (Glass Institute) (Footnote 2). It was established that the melting time of the sintered charge depends on its content of free  $\text{Na}_2\text{SO}_4$  (Fig 1), as well as on the temper-

Card 1/3

The Influence of Thermal Preparation of the Charge on Glass Frits SOV/72-59-10-6/14

ature of the sintered charge (Fig 2). It may be seen from figures 3,4,5, and 6 that vitrification is considerably accelerated during the melting of the sintered charge. The melting time of the initial and the sintered charges is shown in table 1. As may be seen from figure 7, the maximum furnace temperature was 1350°. The chemical analyses of the glasses from the sintered and initial charge are shown in table 2. Experiments showed that at furnace temperatures of from 1350 to 1450°, the entire melting and the refining of glasses from the sintered charge afford better results as compared with the initial charge. Moreover, at equal charge weight, 20% more glass is obtained from the sintered charges than from the initial charge. The chemical analyses of two experimental batches of sintered charges are shown in table 3. By using a cold sintered charge, the furnace output can be increased by 25-30%, and by using a hot charge (at 800-900°), it can be increased by 35-40%, and the time of vitrification and refining can also be considerably reduced. According to indications of Professor N. V. Solomin (Footnote 3), the furnace campaign can be considerably lengthened by using a sintered charge. According

TITLE: The method and device for measuring transmitted power at  
superhigh frequency gm

SOURCE: IVUZ. Radiotekhnika, v. 7, no. 3, 1964, 378-381

TOPIC TAGS: superhigh frequency radiation, transmission line, waveguide, waveguide measuring section, traveling wavepower, power meter, hot cathode diode

ABSTRACT: The described method of measuring the superhigh-frequency field power inside a waveguide is based on the interaction of the wave and a space charge in the waveguide, and has resulted in the design of a simple miniature device for this purpose. A measuring cell forms an essential element of the device and is inserted directly into the waveguide). Because of low inertia, the pulse power and power distribution in the pulse can be registered directly by the device. The described method makes it possible to design field and power

Card 1 / 2

L 6977-65

metals for various ranges from tens of watts to hundreds of kilowatts and higher. The experiments were conducted in the 3-cm band. The investigated circuit consisted of a continuous generation magnetron, attenuator, standing-wave ratio meter, matching transformer, measuring cell (evacuated waveguide section with a stretched tungsten cathode and a diode with the conductive walls), and a 1M-4-type power-monitoring meter. The maximum measured power was 10w. This measuring device with four insulated cathodes, placed in four various waveguide cross sections, can be developed into a four-probe measuring line for power transmission. TITLE: Experience in the use of graphite containing refractory materials for pumping over liquid metals by the electromagnetic method

PERIODICAL: Ogneupory, no. 6, 1961, 292

TEXT: This article deals with the problem of the transportation of liquid metals by means of electromagnetic pumps, for the solution of which high-quality refractory materials are necessary. The high thermal and slag stability, non-wettability by metals and other properties of graphite containing refractory materials led to the assumption that they are suitable for this purpose. The testing of graphite containing refractory materials in steel discharge shutes, made according to the method of the VIO, Vsesoyuznyy institut ogneuporov (All-Union Institute of Refractory Materials) jointly with the Borovichiyskiy kombinat ogneuporov (Borovich Combine of Refractory Materials) showed positive results; the

Experience in the use of graphite ...

graphite containing chamotte products were highly resistant against washing out by the stream of liquid metal, and warranted an increase of the stability of the discharge-shute lining by four to ten times. The All-Union Institute of Refractory Materials, jointly with the avtozavod im. Likhacheva (Automobile Plant imeni Likhachev) experimentally produced a graphite containing chamotte lining for an electromagnetic shute for pumping over liquid crude iron, as well as an electromagnetic measuring hopper in an iron foundry. After three tests of pumping over liquid crude iron, the 6 m long shute lining did not show any signs of wear or destruction. The development of the induction method for pumping liquid crude iron will necessitate the establishment of a special department for the manufacture of graphite containing refractory material. There is 1 figure.

TITLE: A device for checking radiation meters. <sup>19.55</sup> Class 21, No. 174729

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 18, 1965, 57

TOPIC TAGS: radiation monitor, radiometry, radiometer, filter, mercury

ABSTRACT: This Author Certificate presents a device for checking radiation meters. It contains a radiation source, a shielded housing with a collimated channel, an attenuating filter, mechanisms for moving and fixing the position of the source, and an effective area (see Fig. 1). To simplify the design, increase the measurement range, and reduce the checking time, a liquid metal (e.g., Hg) is used as the attenuating filter. The radiation source is placed directly inside the filter and can be moved.

TITLE: The use of polyethylene pipes in pipelines of dosimetric air sampling system <sup>48</sup><sub>45</sub>

SOURCE: Atomnaya energiya, v. 19, no. 2, 1965, 201-203 <sup>B</sup>

TOPIC TAGS: nuclear reactor, atomic energy plant equipment, air pollution control

<sup>19</sup>ABSTRACT: The radioactive-air samplers are usually equipped with pipelines made of aluminum or stainless steel pipes. The possibility of their replacement by non-corrosive polyethylene pipes is discussed. The authors describe their experiments with the polyethylene pipes having a 20 mm diameter and 4 mm wall thickness. The results of their tests showed that the polyethylene pipes could be used at temperatures up to 60 C, pressures up to 3 kg/sq cm and rarefactions of 600 mm Hg. At the beginning of 1962, the air sampling pipelines of the VVR-M reactor were equipped with polyethylene pipes and tubes. Their total length was about 3000 m. No trouble was experienced during two years

TITLE: Tangent channels and reconstruction of thermal column of the  
VVR-M reactor 19

SOURCE: Atomnaya energiya, v. 19, no. 5, 1965, 465-467

TOPIC TAGS: nuclear research reactor, nuclear reactor technology  
 nuclear reactor component/VVR-M nuclear reactor

ABSTRACT: In order to improve the operation of the VVR-M reactor installed at the Physicotechnical Institute im. A. F. Ioffe, some changes were made in the number and disposition of channels and in the rearrangement of thermal column. The reactor was originally provided with 9 horizontal channels located in concrete shielding. In 1961, a channel, No. 10, was added at a distance of 1390 mm from the core center. In 1963, two channels, Nos. 11 and 16, were bored as tangent to the beryllium reflector. Such a tangent position reduced the effect of gamma background on irradiated samples. The thermal column (3040 mm long), originally composed of six graphite disks, was then reconstructed. The

4  
last five graphite disks were replaced by one concrete disk carrying four horizontal channels, No. 13 with  $d = 120$  mm, Nos. 12 and 15 with  $d = 102$  mm and No. 14 with  $d = 80$  mm. Channel No. 14 was bored 10 cm lower than the three upper channels. The arrangement of channels is shown on Card 2/3. The physical parameters on channels Nos. 1, 10, 11 and 16 were given in a table. The addition of channel No. 10 was suggested by Yu. V. Petrov, member of the Institute staff. I.A. Kondurov proposed the channels Nos. 11 and 16. V. S. Gvozdev showed a great activity in creating the tangent channels. A gratitude is expressed to D. M. Kaminker (Scientific Supervisor) for his interest and assistance. Orig. art. has: 2 diagrams and 1 table.

TITLE: Single action KD-1 electromagnetic air valve with switch on signals

SOURCE: Pribery i tekhnika eksperimenta, no. 4, 1966, 224-225

TOPIC TAGS: reactor control, valve, isotope separation, radioactivity measurement, radiation dosimetry, radiation instrument, *ELECTROMAGNETIC PROPERTY*

ABSTRACT: In 1962 the dosimetric control system of the VVR-M reactor was equipped with 65 KD-1 electromagnetic air valves of single action with switch on signals. The valves have been operating continuously for 2 years, each switching at least 50,000 times during this period without a single breakdown. Monthly inspections of the tightness of the air control system disclose that the valves are: overall dimensions - 250 x 120 mm<sup>2</sup>, weight - 4.6 kg, flow-passage cross-sectional area - 16 mm, working voltage - 48 v, type of current - d.c., working current - 0.3 a, signal circuit voltage - 0.5 a, spring pressure on locking piston - 4 kg, stroke of locking piston - 5 mm, temperature of heating surface of valve body at an ambient temperature of +20 C - 45 C, and air leakage at 750 torr - 0.003 l/min, at most. A diagram of the valve is shown below. Orig. art. has: 1 figure.

TITLE: Improvement of the system of stationary dosimetric control of the VVR-M reactor

SOURCE: Atomnaya energiya, v. 21, no. 5, 1966, 386

TOPIC TAGS: nuclear reactor, dosimeter, nuclear reactor operation, nuclear reactor control, radiation dosimetry, nuclear safety/ VVR-M reactor, USIT-1 dosimeter

ABSTRACT: This is a summary of article no. 112/3573, submitted to the editor and filed, but not published in full. The shortcomings of the earlier system are briefly summarized and it is reported that in the improved system, used for the reactor at the Physicotechnical Institute im. A. F. Ioffe, AN SSSR, these shortcomings have been eliminated to a considerable degree. The air-control system has a more highly branched network of sampling lines, with provision made for manual, semi-automatic, and automatic control. Both counter-type and ionization-chamber pickups can be used to determine the concentration of radioactive gases in the air. Control over the exhaust of the radioactive gases is by means of continuous pumping and is continuously monitored by means of an automatic recorder. The  $\gamma$  radiation is monitored by two type USIT-1 instruments, with additional "cactus" type instruments being used in the hot chambers and in the pump room of the first loop and on the cover of the reactor.

Automatic visual and sound alarms are provided. It is claimed that the improved system satisfies present sanitary norms and technological requirements, and that experience accumulated in 2.5 years of operation will lead to further improvements.

TITLE: Vibration Grinding of Hard Alloys

PERIODICAL: Sb. nauchn. tr. Fiz.-tekhn. in-t AN BSSR, 1958, No. 4, pp. 248-255

TEXT: Experiments in using the method of vibration grinding of hard alloys are described. The experiments were performed at FTI AN BSSR. Grinding was carried out with the periphery of a "K360CM2K" (KZ60SM2K) straight-profile grinding disk on a surface-grinding machine. A special electromagnetic vibrator produced the vibratory motion of the "BK8" (VK8) alloy plate in a direction parallel to the disk axis at a frequency of 100 cps and at an amplitude of 2.5 mm. The experiments were performed at a speed of 37.6 m/sec, a longitudinal feed of 3.4 m/min and a grinding depth of 0.08-0.15 mm. Under these conditions, the VK8 alloy plate was subjected to conventional and vibration grinding. In all cases of conventional grinding, cracks and scorches

TITLE: Methods of creating new ways of mechanical tooling of metals

PERIODICAL: Referativnyy zhurnal, Mashinostroyeniye, no. 9, 1961, 42, abstract  
9B266 ("Sb. nauchn. tr. Fiz.-tekhn. in-t AN BSSR", 1959, no. 5,  
158 - 177)

TEXT: The author has developed a method of designing new ways of mechanical tooling based on the principle of the combination of the functional diagrams of cutting. The method is illustrated with the aid of an example of developing a new method of machining cylindrical surfaces. Various cutting systems are analyzed from the viewpoint of a solution of the following problems: chip crushing, deflection of the part being turned, short tool life, unsatisfactory microgeometry of the surface layer and the comparatively low efficiency of the turning method. The most expedient is a combined functional diagram based on the turning with six rotating tools clamped in one common clip (the rotation axis of the tools agrees

TITLE: An Investigation of the Surface Quality at Vibro-Grinding of Hard  
Alloys

PERIODICAL: "Sb. nauchn. tr. Fiz.-tekhn. in-t AN BSSR", 1959, No. 5, pp. 178-188

TEXT: The authors report on the results of investigations of the vibro-grinding process of hard alloys on a universal grinding machine and a surface-grinding machine with vibrators. During the investigation, the roughness of the surface was determined depending on the cutting depth, the table- and cross feed, and the characteristics of the grinding wheel at vibro-grinding (frequency - 100 cps) and without vibrations. It turned out that the vibro-grinding increases the efficiency by 2-3 times; the fine roughness ( $H_{av} = 2-4$  micron) can be obtained with  $t = 0.06 - 0.08$  mm per 2 to-and-fro motions of the table. The vibro-grinding sharply decreases the danger of the appearance of searings and cracks and makes it possible to apply disks of black silicon carbide which yield the same

PERIODICAL: Referativnyy zhurnal, Mashinostroyeniye, no. 5, 1961, 71, abstract  
5B634. (Sb. nauchn. tr. Fiz.-tekhn. in-t, AN BSSR, 1959, no. 5,  
230-235)

TEXT: The authors describe the design and tests of rotary mandrels for the finish machining of internal cylindrical surfaces without removal of chips. The investigation was carried out on specimens of the steel grades 15, 20, 35 and 45 in holes which were reamed by a 1 : 200 tapered reamer, so that the allowance on the diameter continuously varied from 0 to 0.2 mm. The mandrel diameter was 50 mm, the ball diameter 9.5 and 12.7 mm respectively. The investigation showed that the optimum allowance is in the range of 0.08 - 0.1 mm. The surface finish is in the range of the 9th class. There is 1 figure and 6 graphs.

TITLE: An Investigation of Films of Metal Oxide During Grinding and Milling by the Electric Conductivity Method

PERIODICAL: Inzhenerno-fizicheskiy zhurnal, 1959, Nr 7, pp 92 - 95 (USSR)

ABSTRACT: There are statements in previous investigations on the possibility to establish, by means of the electric conductivity method, the nature of an oxide film covering metals in oxidation. In order to check this possibility, the authors studied by this method the films of metal oxides during the milling of St. 45 and cast iron and during the grinding of steel of the 40Kh grade and cast iron. The results of these studies are shown in Figures 2 and 3. As it is seen from these graphs, there is no noticeable decrease of electric conductivity with an increase in the speed of both milling and grinding, if current is fed through a current collector. If, however, current is fed directly into a machine tool without the current collector, a slight decrease of electric conductivity is observed up to a cutting speed of 400 m/min; at a further increase of the cutting speed, electric conductivity rises. A reason for this the authors see in the probable origination of extra-currents of disconnection.

SOURCE: Akademiya nauk Belaruskay SSR. Fiziko-tekhnicheskiy  
institut. Sbornik nauchnykh trudov. no.6. Minsk, 1960.  
216-227

TEXT: In lathe turning operations the chip tends to wind  
itself round the tool and work piece and can be a considerable  
nuisance. Existing types of chip breaker are not reliable, and  
for automatic machines and production lines it is necessary to  
develop new methods of turning which overcome the problem of chip  
breaking. One such method is that in which the cutter is given an  
oscillatory motion in the direction of the feed. Cutting then  
takes place with variable feed and the chips resemble those formed  
during milling. In the Laboratoriya novykh metodov obrabotki  
materialov (Laboratory for new methods of working materials) of the  
FTI AN BSSR an oscillating cutter head was designed for a  
turning lathe type 1A62. The construction

E194/E135

is illustrated schematically in Fig.1. The tool 1 in the tool holder 2 is made to oscillate along the axis of the work piece by the cam 3 which is driven along a spline shaft 4 through the gearing 5. The tool holder is held against the cam by springs. The amplitude of oscillation is altered by changing the cam shape but a fine adjustment 7 is also provided. In another design the cam was driven by a separate motor of 0.6 kW. The tests were made with cutters tipped with the carbides T5 K10 and T15K6 working steels 20, 45 and 18XГТ (18KhGT). The cutter geometry was:

- a)  $\varphi = 90^\circ$ ;  $\varphi_1 = 60^\circ$ ;  $\lambda = 0^\circ$ ;  $\gamma = 7^\circ$ ;  $\alpha = 11^\circ$ ;  $r = 0.5 \text{ mm}$ ;  
b)  $\varphi = 60^\circ$ ;  $\varphi_1 = 26^\circ$ ;  $\lambda = 0^\circ$ ;  $\gamma = 7^\circ$ ;  $\alpha = 11^\circ$ ;  $r = 0.5 \text{ mm}$ .

[Abstractor's note: In Soviet terminology  $\varphi$  = plan angle,  $\varphi$  = working trail angle,  $\lambda$  = cutting edge side rake,  $\gamma$  = rake and  $\alpha$  = clearance;  $r$  is presumably nose radius.]

Theoretical formulae are derived for the instantaneous rate of feed of the oscillating cutter and expressions are derived for the conditions when the feed is zero so that the chip must break. Then an expression is obtained for the amplitude necessary to cause chip breakage. However, the actual amplitude differs from that calculated because of elastic vibration of the lathe, the tool and

Card 2/8

Certain operating characteristics ... <sup>30946</sup> S/571/60/000/006/011/011  
E194/E135

the part and moreover it is not always necessary to reduce the feed to zero to ensure chip breaking. Accordingly, tests were made to ensure chip breakage under different cutting conditions. The amplitude of oscillation was measured by a vibrograph which recorded on a moving tape fitted on the tool holder. Fig.2 shows a graph of the minimum amplitude in mm as function of the feed rate in mm/rev. for steel grade 18KhGT (dotted line) and steel 45 (solid line). It is found that the minimum amplitude to ensure chip breakage is greater than the calculated value by some 20-30%. In the case of the tough steel grade 18KhGT the minimum amplitude is proportional to the feed; however, for steel grade 45 at feeds greater than 0.25 mm/rev. proportionality is not observed. This is because the break occurs where the chip is thin. Further tests showed that the use of emulsified cutting oils reduced the stable value of the minimum amplitude. The minimum amplitude is increased with increasing depth of cut. However, changes in the cutting speed (in the range 62-190 metres/min) or in the rake angle of the cutter (from  $-5^\circ$  to  $+15^\circ$ ) or in the cutting edge side rake ( $-5^\circ$  to  $+15^\circ$ ) have practically no influence on the minimum amplitudes. By introducing empirical coefficients into the

Card 3/8

Certain operating characteristics ... <sup>30916</sup> S/571/60/000/006/011/011  
E194/E135

theoretical formula the following expression is obtained for the minimum amplitude necessary to ensure chip breaking:

$$A_{\min} = q_{\varphi} q_t q_o q_{\kappa} \frac{S}{1.5 \left| \sin \pi \frac{f}{n} \right|} \text{ mm} \quad (7)$$

where values of  $q$  are taken from Table 1.  
When an oscillating cutter is used the finish is not so fine as with a normal tool. It was found that the smoothest surface was obtained for ratios of oscillation frequency to spindle speed which give the minimum amplitude for chip breaking, i.e. when this ratio is 0.5, 1.5 or 2.5. Fig.7 shows a graph of the relationship between the surface roughness in microns and the ratio of the frequency of oscillation to the spindle speed where  $V = 70 \text{ m/min}$ ,  $S = 0.5 \text{ mm/rev.}$ ,  $t = 2 \text{ mm}$ , using steel grade 45. The dotted line shows the surface roughness with normal cutting methods. The influences of feed, cutting speed and use of cutting fluid and depth of cut on surface finish with an oscillating cutter are much the same as with an ordinary tool. The variations in rate of feed with an oscillating cutter would tend to promote tool wear, and so

Card 4/8

Certain operating characteristics ...

<sup>30946</sup>  
S/571/60/000/006/011/011  
E194/E135

will the increase in the impact loading. On the other hand, with an oscillating cutter the cutting edge periodically leaves the cutting zone so that it runs cooler. This was confirmed by measuring the electromotive force between tool and workpiece which was less with an oscillating cutter than with a normal tool. Tool wear studies showed that with an oscillating cutter in the majority of cases the tool performance was 30-40% better than with a normal tool. It is considered that an oscillating cutter can be successfully used on ordinary turning lathes and it is particularly effective when used on automatics or on automatic lines. There are 11 figures, 1 table and 6 Soviet-bloc references. X

TITLE: On the penetration of cutting fluid into the cutting region during mechanical metal-working

PERIODICAL: Akademiya nauk Bielorussskoy SSR. Izvestiya. Seriya fiziko-tekhnicheskikh nauk. no. 3, 1961, 115-119

TEXT: The effect of vibrations on the cutting process is considered. In the authors' opinion, the vibrations which arise in metal cutting facilitate the penetration of the cutting fluid into the cutting zone, thereby wear is reduced and the metal working improved; this applies to vibrations of small amplitude and high frequency (ultrasonic). This hypothesis was verified by means of special experimental procedure. The vibrations were generated by the ultrasonic generator Y3M-1.5 (UZM-1.5) of power 1.5 kilowatt. Three types of cutting fluid were investigated: ordinary water, an emulsion and cutting oil. The height of the fluid column in capillary tubes was investigated after connecting and disconnecting

TITLE: A new method for gauging ring-shaped parts

SOURCE: Akademiya nauk Belaruskay SSR. Fiziko-technicheskiy  
institut. Sbornik nauchnykh trudov. no.7. 1961. 184-189

TEXT: A new, simplified method for the fine adjustment of the internal and external diameters of cast, stamped, forged, or sintered metal parts, are described; the diameters are adjusted through plastic deformation alone, using a die for the external diameter and a floating, round-headed plunger for the internal diameter, on a 40-ton hydraulic press. The dies and plunger are made of a hardened X3F (KhVG) alloy (Cr-W-Mn), and their surfaces are finished to a high degree of smoothness. In experiments with sintered ring-shaped parts consisting of perlite + 10-15% ferrite (Brinell hardness 50-70 kg./sq.mm.) external diameters ranging from 34.12 to 34.26 mm. were adjusted to 33.94 to 33.98 mm. while internal diameters ranging from 16.95 to 17.03 mm. were adjusted to 16.98

TITLE: An investigation of the depth of the strain-hardened layer and the wear-resistance of the hardened surface after rotary ball-burnishing of internal cylindrical surfaces

SOURCE: Akademiya nauk Belaruskay SSR. Fiziko-tekhnicheskiy institut. Sbornik nauchnykh trudov. no.7. 1961. 200-203 ✓

TEXT: Rotary ball-burnishing is a new cold-working process producing plastic deformation in metallic surfaces with a consequent increase in hardness; the process is described in the book "Rotatsionnoe dornirovanie", by the same authors, published by the BSSR Academy of Sciences, 1959. The depth of the strain-hardened layer produced is practically independent of variations in the rate of burnishing within the range 50-500 m./min., and increases slightly with a decreased ball diameter. The maximum depth produced under optimum conditions is 1.9-2.2 mm. in steel Cm-15

TITLE: The effect of high frequency (ultrasonic) vibrations on the passage of liquid media through capillary channels

SOURCE: AN UkrSSR. Institut metallokeramiki i spetsial'nykh splavov. Poverkhnostnyye yavleniya v rasplavakh i protsessakh poroshkovoy metallurgii (surface phenomena in liquid metals and processes in powder metallurgy). Kiev, Izd-vo AN UkrSSR, 1963, 192-198

TOPIC TAGS: high frequency vibration, ultrasonic vibration, capillary channel, liquid medium

ABSTRACT: In this paper, the authors studied the effect of ultrasonic vibrations under various conditions (capillary diameter, temperature) on a liquid medium in a capillary channel. The results are presented in graphs. Ultrasonic influence on the passage of liquid media through capillary channels is a new, little studied phenomenon. Only the first steps have been made in the study of this problem; before it lies even greater efforts. Many questions still must be answered in order to explain the physical nature of this phenomenon and its practical application in industry. It

TITLE: The influence of temperature on the rise of liquid in a capillary under the action of high frequency vibrations

PERIODICAL: Inzhenerno-fizicheskiy zhurnal, v. 6, no. 3, 1963, 103 - 105

TEXT: The capillary rise of a liquid is largely determined by the surface tension of the liquid and consequently decreases with increasing temperature. If the liquid vibrates with ultrasonic frequencies in the direction of the capillary axes, the rise is greater and increases with temperature. Water, an emulsion of commercial acidol, and lubricating oil were subjected to 23.5 kcs in glass tubes of various diameters. The increase in capillary rise was measured in the 0 - 80°C range. The height to which water rises in a capillary tube with an inner diameter of 0.484 mm increases from 30 mm at  $\approx 5^{\circ}\text{C}$  to 90 mm at  $\approx 70^{\circ}\text{C}$ . Similar results are obtained for other liquids under different conditions. There are 2 figures.

CITED SOURCE: Sb. Primeneniye ul'trazvuka v mashinostr. Minsk, Nauka i tekhnika, 1964, 22-26

TOPIC TAGS: copper, ultrasonic inspection

TRANSLATION: The effect of tensile strength and compression on the microhardness of copper were investigated. The study was carried out at a constant 20 kc oscillation frequency and various amplitudes, on a sample face: 0.012, 0.008 and 0.006 mm. This accordingly produced the following stresses in the central part of the sample: 17.0, 11.40, 8.55 kg/mm<sup>2</sup>. The samples were tested in two states: (1) annealed at 550°C for 2 hrs, and (2) previously deformed (strain hardened) by torsion (φ720 and 1440°). The microhardness of the annealed Cu increases sharply with an increase in the number of cycles at the beginning, dropping slightly thereafter. However, it remains constantly higher than the initial one. The difference in the strain hardening and softening processes is the more noticeable the higher the cyclic stress.

TITLE: Effect of ultrasonic frequency oscillation on the creep characteristics of D16 aluminum alloy

CITED SOURCE: Sb. Primeneniye ul'trazvuka v mashinostr. Minak, Nauka i tekhnika, 1964, 41-46

TOPIC TAGS: ~~ultrasonic~~, ultrasonic vibration, ultrasonic ~~test~~ inspection, aluminum alloy, creep, annealing, material deformation/D16T aluminum alloy

TRANSLATION: The effect of HF-oscillation and the simultaneous application of a static load ( $\sigma_{st} 6.5k/mm^2$ ) were studied in testing D16T alloy, annealed at 370°C (5 hrs) for creep. Applying oscillation during test for creep simultaneously with a static load increases the total creep deformation and the rate of creep, especially in the initial stage of the test. The preliminary application of ultrasonic oscillations strengthens the D16T aluminum alloy slightly. This is expressed in a decrease in the rate and the total deformation of creep. 9 references.

TOPIC TAGS: ultrasonic inspection, ultrasonic vibration, alloy, ~~alloy steel~~, copper, solid mechanical property, low carbon steel / D16T alloy  
TRANSLATION: Methods and the results are given of an investigation of the effect of ultrasonic frequency oscillations on the mechanical properties of D16T alloy, copper, and iron on tensile strength, torsion and creep. The simultaneous effect of cyclic and static loads, created by ultrasonic oscillations during tensile strength test of D16T alloy and copper (Cu-99.90%), shows a significant decrease in their mechanical characteristics. For example: the  $\sigma_b$  for the D16T-alloy (tempered and naturally aged) decreases from 5 to 16%, whereas the magnitude of the  $\sigma_b$  decrease is a function of the oscillation amplitude. Also, during torsion test of D16T-alloy and low-carbon steel (0.06%C) the ultrasonic oscillations considerably decrease their mechanical characteristics. The application of the ultrasonic frequency oscillation to a static

Effect of ultrasound on the process of eliminating commercial iron

AN BSSR, Fiziko-tekhnicheskiy institut. Plastichnost' i obrabotka  
pod davleniyem (Plasticity and metalworking by pressure). Minsk, Izd-vo  
Nauka i tekhnika, 1964, 91-97

TOPIC TAGS: ultrasound, tensile testing, yield point, low carbon steel, stress  
raiser, commercial iron, stress elimination

ABSTRACT: This article describes investigations of the effect of ultrasonic vi-  
brations on the strength and ductility of commercial iron, the primary feature  
of the tests being that the static and vibratory loads were applied simultane-  
ously during elongation of the specimen. An ultrasonic generator with a magneto-  
dynamic oscillator operating at 21 kc was used as the source of the vibratory  
ultrasonic frequency. The amplitude of the oscillations was measured at  
the end of the specimen by a microscope. The test specimens were made out of  
steel rods, annealed in a vacuum at 600C for 3 hrs, cooled down with the

Card 1/2

19983-65

2

ACCESSION NR: AT5006708

turnace to 400 C, and then cooled in air. The tensile tests were carried out at  
zation rate of 10 mm/min. The investigation revealed that the superposi-  
tion of vibrations on the process of elongation of commercial iron  
all its mechanical properties, this is depending on the amplitude of  
vibrations. Strain can therefore be reduced by ultrasound during various  
stages of pressure working of metals. Orig. article has 1 table, 4 figures  
and 1 formula.

TITLE: Investigation of the process of static torsion of D16T alloy in an ultra-  
 sonic field at elevated temperatures

SOURCE: AN BSSR. Fiziko-tekhnicheskiiy institut. Plastichnost' i obrabotka  
 metallov davleniyem (Plasticity and metalworking by pressure). Minsk, Izd-vo  
 Nauka i tekhnika, 1964, 102-103 /S

TOPIC TAGS: static torsion, torsional strength, ultrasound, aluminum alloy /  
 D16T alloy

ABSTRACT: The results of studies on the effect of ultrasonic vibrations on the  
 process of static torsion in D16T alloy at elevated temperatures are given. The  
 testpieces were annealed at 360C for 5 hrs. and cooled down with the furnace to  
 room temperature. The working length of the specimen was 70 mm and the diameter  
 10 mm. The experiments were carried out with and without the specimens being  
 cooled by running water. Since the torsional strength in both cases was the same,  
 it was evident that heat liberation in the specimen owing to the absorption of

Card 1/2

2

ACCESSION NR: AT5006709

ultrasound was negligible. The temperature of deformation varied from 20 to 100, 150, 200, 250 and 300C. It was found that the process of static torsion of annealed D16T alloy in an ultrasonic field with an amplitude of vibration of 0.006 mm at the end of the specimen led to a decrease in the true torsional strength by 3.4 kg/mm<sup>2</sup>, with this difference remaining constant over the entire range of test temperatures. ABSTRACT: This article describes a device for creep tests with the application of ultrasonic vibrations and gives the results of an investigation of the effect of preliminary treatment with ultrasound on the creep characteristics of D16T alloy at 250C. The device, which is a modernized version of the VIA-11 table-model machine for testing creep, is depicted and described in detail. 10 specimens were exposed to ultrasonic radiation in the air for 15, 30, 45, and 60 seconds after which they were placed in the machine, heated for an

hour, and then creep tested for 90 min. at 250C with the application of only a static load. The creep tests on previously sonicated specimens of D16T aluminum alloy demonstrated that the creep rate drops markedly due to work hardening of the material during exposure to ultrasonic waves. TITLE: Ultrasonic removal of stresses in parts after plastic deformation

SOURCE: AN ESSR. Fiziko-tekhnicheskiy institut. Plastichnost' i obrabotka  
 metallov davleniyem (Plasticity and metal working by pressure). Minsk, Izd-vo  
 Nauka i tekhnika, 1964, 202-204

TOPIC TAGS: plastic deformation, ultrasonic treatment, reeling, stress elimina-  
 tion

ABSTRACT: The purpose of this article was to find a method for removing internal  
 stresses after reeling cylinders so that the dimension of the cylinder remained  
 constant after removing the enveloping ring, which is used to protect the opening  
 of the cylinder skirt against distortion during reeling. The ultrasonic method  
 was selected since the work-hardened surface of the cylinder opening after reel-  
 ing was thermodynamically unstable and ultrasonic vibrations always promote the  
 transition of metal from a thermodynamically unstable state to a more stable one  
 by removing internal stresses. Twenty-two cylinders were reeled with enveloping

rings on the skirt. After reeling, the inside diameter of the cylinder skirt was measured again. The other 11 cylinders were exposed to ultrasonic radiation for 10 min, after which the rings were removed from the cylinder skirts and the inside diameter measured. After reeling, the size of the cylinders at the place of the skirt with the enveloping rings had average deviations from the nominal size of 0.044-0.061 mm. The size changed (on the average by up to 0.078 mm) after removal of the ring. In the cylinders which were exposed to ultrasound and whose rings were then removed, the size decreased 0.024 mm. The authors therefore conclude that ultrasonic vibrations eliminate internal stresses after reeling. Orig. art. has: 1 table.

Metallurg, Ye. G.; Kozlovskiy, I. I.  
 Effect of the amplitude of high frequency oscillations on  
 properties of copper

A study was made of the effect of high frequency  
 oscillations on the properties of copper. The  
 samples were set up through a type PM3-7 magnetostrictive  
 generator. The amplitudes of  
 exposure to sound waves were varied as follows:
